Moral Identity, Moral Disengagement and Anticipated Guilt
Predict Doping Likelihood in Amateur Athletes

Maria Kavussanu & Christopher Ring
University of Birmingham, UK

Accepted for Publication on 1 October, 2017
by Journal of Sport and Exercise Psychology

Abstract

In this study, we integrated elements of social cognitive theory of moral thought and action (Bandura, 1991) and the social cognitive model of moral identity (Aquino & Reed, 2002) to better understand doping likelihood in amateur athletes. Participants (N = 398) recruited from a variety of team sports completed measures of moral identity, moral disengagement, anticipated guilt and doping likelihood. Moral identity predicted doping likelihood indirectly via moral disengagement and anticipated guilt. Anticipated guilt about potential doping mediated the relationship between moral disengagement and doping likelihood. Our findings provide novel evidence to suggest that athletes, who feel that being a moral person is central to their self-concept are less likely to use banned substances due to their lower tendency to morally disengage and the more intense feelings of guilt they expect to experience for using banned substances.

Keywords: affective self-sanction; social cognitive theory; banned substances

Moral Identity, Moral Disengagement and Guilt Predict Doping Likelihood in Amateur Athletes

The psychological factors associated with the use of banned performance-enhancing substances or methods in sport, also known as doping, have received increased research attention in recent years (see Ntoumanis, Ng, Barkoukis, & Backhouse, 2014). Identifying such factors is important, as this knowledge would enable us to design interventions to prevent doping in sport. There is growing evidence that not only professional but also amateur athletes consume banned performance-enhancing substances (e.g., Locquet et al., 2017; Zabala, Morente-Sánchez, Mateo-March, & Sanabria, 2016). Therefore, research into doping in amateur competitive athletes is important. A number of psychological models have been proposed to explain doping in sport (e.g., Barkoukis, Lazuras, & Tsorbatzoudis, 2016; Donovan, Egger, Kapernick, & Mendoza, 2002). The aim of the present research was to extend previous work by testing a model of doping based on Bandura's (1991) social cognitive theory of moral thought and action and the socio-cognitive model of moral identity (Aquino & Reed, 2002).

Social Cognitive Theory and Doping

Bandura (1991) proposed that individuals develop moral standards through socialization experiences and interaction with others, for example, by observing significant others and through reinforcement and punishment. These moral standards help regulate behavior via evaluative affective self-reactions. People feel satisfaction and pride when they act in line with their moral standards, and experience negative emotions, such as shame or guilt, when they do not act in line with these standards. These self-sanctions regulate behavior anticipatorily, whereby individuals tend to avoid behaviors that will evoke self-condemnation (Bandura, 1991, 2002). Thus, anticipated negative emotion is a key regulator of unethical behavior. Indeed, anticipated negative feelings (e.g., guilt, regret, shame) about

possible doping have been negatively associated with doping intentions¹ in adolescent and adult athletes (Barkoukis, Lazuras, & Harris, 2015; Lazuras, Barkoukis, & Tsorbatzoudis, 2015; Ring & Kavussanu, 2017).

Although moral standards are assumed to regulate behavior via affective self-sanctions, people do not always act as they should. They are able to engage in transgressive behavior without feeling bad about it, via the use of cognitive mechanisms, known as moral disengagement. Bandura (1991, 1999) described eight mechanisms of moral disengagement; however, only six are relevant to doping (see Kavussanu, 2016; Kavussanu, Hatzigeorgiadis, Elbe, & Ring, 2016; Lucidi et al., 2008; Mallia et al., 2016). These are: (a) moral justification, for example, doping is justified as done for a higher social purpose, such as to feed one's family or to help one's country; (b) advantageous comparison, when doping is contrasted to other less severe behaviors, thereby appearing not as serious; (c) euphemistic labeling, when athletes who dope use sanitizing language by referring to doping as "juice" or to EPO as "altitude training in a bottle"; (d) diffusion of responsibility (e.g., "everyone in the team is doing it"); (e) displacement of responsibility, where responsibility for one's transgressive behavior is displaced on others (e.g., "my coach told me to do it"); and (f) distortion of consequences, for example, when athletes downplay the negative consequences of their transgressive behavior for others. Moral disengagement has been positively associated with both doping temptation (Hodge, Hargreaves, Gerrard, & Lonsdale, 2013) and doping intentions in several studies (Kavussanu et al., 2016; Ntoumanis, Barkoukis, Gucciardi, & Chan, 2017; Ring & Kavussanu, 2017; Zelli, Mallia, & Lucidi, 2010).

As indicated above, Bandura (1991) proposed that moral disengagement enables individuals to engage in transgressive behavior, by reducing the anticipated negative affective reactions, such as guilt, which would normally arise from engaging in such behavior. Guilt, a self-conscious moral emotion arising from moral transgression, is a key regulator of moral

action (Tangney, Stuewig, & Mashek, 2007; Zebel, Doosje, & Spears, 2009). In his seminal study, which examined moral disengagement empirically, Bandura and colleagues (Bandura, Barbaranelli, Caprara, & Pastorelli, 1996) reported that moral disengagement was a negative predictor of anticipated guilt, which in turn negatively predicted aggressive behavior in school children. In the context of sport, Stanger, Kavussanu, Boardley and Ring (2013) showed that moral disengagement predicted athletes' antisocial behavior both directly and indirectly via anticipated guilt. However, to date, only one study has investigated the mediating role of anticipated guilt in the relationship between moral disengagement and doping likelihood. Specifically, Ring and Kavussanu (2017) found evidence consistent with this mediating role in a sample of university athletes. There is a need to determine whether these findings are replicated in a larger, independent sample of athletes, from a more diverse age group, that is more representative of adult sport. In addition, research is needed to identify factors that influence moral disengagement.

Moral Identity and Doping

Building, in part, on the social cognitive model of moral behavior (Bandura, 1991), Aquino and Reed (2002) described the psychological construct of moral identity, as a self-regulatory mechanism. They defined moral identity as “a self-conception organized around a set of moral traits” (Aquino & Reed, 2002, p. 1424) and proposed that people vary in the degree to which they consider being a good or moral person a central part of their self-concept. Moral identity is a strong source of moral motivation, that is, the motive to behave morally, due to individuals' desire to maintain consistency between conceptions of their moral self and their actions (Aquino, Freeman, Reed, Lim, & Felps, 2009; Blasi, 1984). Indeed, individuals whose moral identity was central to their self-concept were less likely to lie in a salary negotiation (Aquino et al., 2009) and more likely to avoid antisocial behavior (Hertz & Krettenauer, 2016). In the context of sport, athletes with strong moral identity

1 reported less frequent antisocial behavior toward their opponents (Kavussanu, Stanger, &
2 Boardley, 2013; Kavussanu, Stanger, & Ring, 2015). However, to date, no study has
3 investigated whether moral identity predicts the doping likelihood in sport.

4 Moral identity could deter individuals from doping by acting on the two variables
5 discussed in the previous section, namely moral disengagement and anticipated guilt. It is
6 reasonable to expect that the individual, who places high importance on being a moral
7 person, should experience more guilt, if he or she behaved badly, as this behavior would not
8 be compatible with the person's view of the self as moral. Indeed, moral identity was
9 positively associated with anticipated guilt in athletes, who were faced with the possibility of
10 acting antisocially, in both cross-sectional and experimental research (Kavussanu et al., 2013,
11 2015). Moral identity should also reduce the tendency to morally disengage, as one would
12 be motivated to act morally, in order to keep one's actions in line with one's self-concept as
13 a moral person, therefore not needing to justify unethical behavior. Indeed, moral identity
14 has been inversely associated with moral disengagement in past research (Detert, Trevino, &
15 Sweitzer, 2008; Kavussanu et al., 2016).

16 **The Present Research**

17 Considerable research evidence has been accumulated indicating that moral
18 disengagement is positively related to doping variables (e.g., Hodge et al., 2013; Kavussanu et
19 al., 2016; Ntoumanis et al., 2017). However, to date, only one study has investigated
20 whether anticipated guilt mediates the relationship between moral disengagement and
21 doping likelihood (Ring & Kavussanu, 2017). This study used exclusively university athletes,
22 of a limited age range, thus their findings have limited generalizability. Therefore, the first
23 purpose of this study was to examine whether anticipated guilt mediates the relationship
24 between moral disengagement and doping likelihood in an independent and more diverse
25 sample of athletes. We expected to replicate findings of previous research (Ring &

Kavussanu, 2017). The second purpose of this study was to investigate whether moral identity is associated with doping likelihood and whether this relationship is mediated by moral disengagement and anticipated guilt. Based on previous findings on antisocial sport behavior (Kavussanu et al., 2013, 2015), we hypothesized that moral identity would be inversely associated with doping likelihood, and that this relationship would be mediated by moral disengagement and guilt (e.g., Detert et al., 2008; Kavussanu et al., 2015).

Method

Participants

Participants were 398 (233 males) club and college athletes participating in five team sports (netball, rugby, football, basketball, korfbal) recruited from competitive adult regional ($n = 281$; 70.6%) and college (Division I and II) leagues in the West Midlands region of the United Kingdom. At the time of data collection, participants ranged in age from 16² to 40 years, had competed in their sport for an average of 9.06 ($SD = 4.22$) years, had played for their current team for an average of 2.88 ($SD = 3.11$) years, and had played under their current coach for an average of 2.35 ($SD = 2.69$) years.

Measures

Doping likelihood.

One of the difficulties in doping research is that doping is an illegitimate behavior, to which athletes are naturally reluctant to admit. To circumvent this issue, most researchers measure variables such as doping intentions (e.g., Lazuras et al., 2015), temptation (Hodge et al., 2013; Ntoumanis et al., 2017) or likelihood (e.g., Kavussanu et al., 2016), as proxies for doping behavior. In line with previous research (Kavussanu et al., 2016; Ring & Kavussanu, 2017), we asked participants to report their likelihood of doping in two hypothetical situations, in which they could use a banned substance to (a) enhance performance and (b) aid recovery from injury³. These two scenarios were used because consultation with elite

1 athletes suggested that fitness-related performance enhancement and injury recovery are
2 two of the most common reasons athletes decide to use banned substances (also see
3 Huybers & Mazanov, 2012; Whitaker & Backhouse, 2016).

4 The performance-enhancement scenario read as follows: "It is the day before the most
5 important game of the season. The winner of this game will win the league. The team against
6 which you will compete is of similar ability level to your team, and they are just one point
7 ahead of your team in the league. Lately, your performance has been below your best. You
8 don't feel you have the necessary fitness for this important game, and you are concerned
9 about how you will perform. You mention this to one of your teammates, who tells you
10 that he/she has been using a new substance, which has enhanced his/her fitness and, as a
11 result, his/her performance. The substance is banned for use in sport, but the chance that
12 you will be caught is extremely small."

13 The injury recovery scenario read as follows: "It is two weeks before the most
14 important game of the season. The winner of this game will win the league. The team against
15 which you will compete is of similar ability level to your team and they are just one point
16 ahead of your team in the league. You really want to play in this game. However, two
17 months ago, you sustained a knee injury, and you know you need at least one more month
18 of rehabilitation to fully recover. One of your teammates tells you that he/she has recently
19 used a new substance, which has helped him/her recover faster than usual from a knee
20 injury. The substance is banned for use in sport, but the chance that you will be caught is
21 extremely small."

22 After reading each scenario, participants indicated the likelihood that they would use
23 the banned substance on a Likert scale, anchored by 1 (*not at all likely*) and 7 (*very likely*).
24 Although the mean ratings for the injury scenario were higher than those of the
25 performance-enhancing scenario, these ratings were also highly related to each other ($r =$

.71, $p < .001$); thus, the average of the two ratings was used to measure doping likelihood. The internal consistency of the scores of this combined measure was very good ($\alpha = .81$).

Moral disengagement.

The moral disengagement in doping scale (Kavussanu et al., 2016) was used to measure doping moral disengagement. Participants were asked to indicate their level of agreement with six statements (e.g., “Doping does not really hurt anyone”, “Compared to the illegal things people do in everyday life, doping in sport is not very serious”) using a Likert scale, anchored by 1 (*strongly disagree*) and 7 (*strongly agree*). The scale has shown good internal consistency ($\alpha = .78 - .86$), test-retest reliability ($r = .78$), and factorial, convergent, and concurrent validity (Kavussanu et al., 2016). The mean of the six item ratings was computed and used as a measure of doping moral disengagement; internal consistency of the scale scores in the present study was good ($\alpha = .75$).

Moral identity.

The internalization dimension of the moral identity scale (Aquino & Reed, 2002) was used to measure moral identity. Participants were presented with nine traits (e.g., fair, honest, helpful, kind, generous, compassionate, etc) considered common characteristics of moral persons and were asked to respond to five statements concerning these traits (e.g., “It would make me feel good to be a person who has these characteristics”) on a Likert scale, anchored by 1 (*strongly disagree*) and 7 (*strongly agree*). This scale has shown very good internal consistency in previous research ($\alpha = .83$; Aquino & Reed, 2002). The mean of the five item ratings was computed and used as a measure of moral identity; internal consistency of the scale scores was very good ($\alpha = .81$).

Procedure

After obtaining ethical approval, participants were recruited from sports teams participating in local competitive leagues and university teams in the UK. Data were

collected by research assistants either at the beginning or at the end of a training session. Participants were instructed to complete the questionnaires as carefully as possible. They were informed about the study's aims, that participation was voluntary, honesty in responses was vital, and data would be kept strictly confidential and used only for research purposes. Next, participants indicated consent with taking part in the study and completed the questionnaires described above. The questionnaires were completed anonymously and without the coach present to minimise socially-desirable responding.

Results

Preliminary Analyses

Prior to our main data analysis, we conducted preliminary analyses to examine missing values, outliers, normality, skewness, kurtosis and internal consistency of the scales (Tabachnick & Fidell, 2007). These analyses indicated that 0.2% of the data points were missing. When less than 5% of the data are missing, any method for replacing missing data is acceptable (Tabachnick & Fidell, 2007); therefore, we replaced missing data with the series mean. There were no outliers, identified as scores more than 3.29 SD from the mean. Skewness and kurtosis were low (i.e., < 2) for all variables (Tabachnick & Fidell, 2007). All scale scores exhibited good internal consistency (see Table I).

Descriptive Statistics and Zero-Order Correlations

The mean measure scores (Table I) showed that players were characterized by relatively high moral identity, low moral disengagement, and high anticipated guilt, and were not likely to use banned substances. The zero-order correlations indicated that moral identity was negatively associated with doping likelihood and moral disengagement, and positively associated with anticipated guilt. Doping likelihood was also positively associated with moral disengagement and negatively associated with guilt.

Main Analyses

The first purpose of this study was to determine whether anticipated guilt mediates the relationship between moral disengagement and doping likelihood, in line with previous research (Ring & Kavussanu, 2017). The second purpose was to examine whether moral identity was associated with doping likelihood and whether this relationship was mediated by moral disengagement and anticipated guilt. We examined both purposes in a single model using the PROCESS 2.16 (Hayes, 2013) SPSS macro (model 6), which simultaneously tests direct and indirect effects, in serial mediation models. Direct effects are the effects of the predictor on the outcome variable that occur independently of the mediator(s), while indirect effects are the effects of the predictor on the outcome variable via the mediator(s). Bootstrapping was set at 10,000 samples. Bias corrected 95% Confidence Intervals (CI) were estimated for all effects. An effect was significant when the CI did not contain zero. The Completely Standardized Indirect Effect (CSIE) was reported as the effect size metric (Preacher & Kelley, 2011), with values of .01, .09, and .25 representing small, medium, and large effect sizes, respectively (Cohen, 1992).

Results of these analyses are presented in Table 2 and Figure 1. With respect to the first study purpose, it can be seen that anticipated guilt significantly mediated the relationship between moral disengagement and doping likelihood: indirect effect = .40, 95% CI = .31, .50; CSIE = .28, 95% CI = .22, .35. Moral disengagement had a strong negative effect on anticipated guilt, which also had a negative effect on doping likelihood. With respect to the second study purpose, moral identity was not directly related to doping likelihood in the model (Table 2, Figure 1). Results of mediation analysis (Table 2 and Figure 1) show that moral identity had a direct negative effect on moral disengagement and a positive effect on guilt. Importantly, moral identity had significant indirect effects on doping likelihood via moral disengagement, anticipated guilt, and moral disengagement, then guilt (see Table 2). These findings provide support for the mediating role of both moral disengagement and

1 anticipated guilt on the relationship between moral identity and doping likelihood. Overall,
2 the model accounted for 59% of the variance in doping likelihood, $F(4, 394) = 186.11$, $p <$
3 $.001$, $R = .77$.

4 Discussion

5 Bandura's (1991) social cognitive theory of moral thought and action provides a useful
6 theoretical framework to help understand doping in sport. In this study, we integrated
7 elements from the social cognitive theory and the model of moral identity proffered by
8 Aquino and Reed (2002) to examine doping likelihood in amateur athletes. Specifically, we
9 investigated whether moral identity predicted doping likelihood both directly and indirectly
10 via moral disengagement and/or anticipated guilt in a sample of college and club-level
11 athletes.

12 Moral Disengagement and Doping

13 In support of our hypothesis, we found that the relationship between moral
14 disengagement and doping likelihood was mediated by anticipated guilt. Moral
15 disengagement was a negative predictor of anticipated guilt, which in turn negatively
16 predicted doping likelihood. This mediation pathway has also been revealed in previous
17 research examining doping likelihood in athletes (Ring & Kavussanu, 2017) and other forms
18 of transgressive behavior in sport (e.g., Stanger et al., 2013) and school (e.g., Bandura et al.,
19 1996). This finding supports a main tenet of social cognitive theory (Bandura, 1991), namely
20 that moral disengagement enables individuals to engage in transgressive conduct by reducing
21 the anticipated affective self-sanctions, typically associated with such conduct.

22 Our result highlights the important role of emotion on doping. The moral emotion of
23 guilt is elicited by moral transgressions and is assumed to regulate behavior because people
24 strive to minimize affective dissonance elicited by threats to the moral self (e.g., Tangney et
25 al., 2007). Other studies have also reported that anticipated regret and guilt about potential

doping were inversely associated with doping intentions (e.g., Barkoukis et al., 2015; Lazuras et al., 2015; Ring & Kavussanu, 2017). Taken together with past work, our findings suggest that negatively-valenced self-conscious emotions such as guilt can act as self-sanction that thwarts doping by athletes.

In addition to the indirect effect via anticipated guilt, moral disengagement also had a direct effect on doping likelihood suggesting that guilt may only partially mediate the relationship between the two variables. Thus, moral disengagement may operate on doping likelihood via other processes, besides reducing guilt, for example, by promoting positively valenced emotions. Specifically, it is possible that reframing an act as laudatory or praiseworthy may bring positive affective responses into play in support of committing the unethical act of doping. It is also possible that simply morally disengaging enables athletes to use banned substances. In a recent meta-analysis (Ntoumanis et al., 2014), moral disengagement was one of the strongest and most reliable predictors of doping variables. The tendency to use rationalizations for cheating could facilitate cheating behavior, and anticipated guilt may not be the only variable that plays a role in this process.

It is also worth noting that we causally ordered our variables to be in line with the seminal work by Bandura et al (1996) investigating moral disengagement as a predictor of transgressive behavior, in school children, as well as with previous cross-sectional (e.g., Boardley & Kavussanu, 2009, 2010; d'Arripe-Longueville et al., 2010; Hodge et al., 2013) and experimental (Stanger et al., 2013) sport research, treating moral disengagement as an antecedent of transgressive behavior in sport. However, moral disengagement could also follow transgressive behavior. That is, once a person has committed a transgression, the need to alleviate the ensuing negative affect should trigger the use of moral disengagement mechanisms. Indeed, a recent study showed that moral disengagement increased after participants cheated during an experiment (Shu, Gino, & Bazerman, 2011). It would be

1 interesting to determine, in a single study, the degree to which moral disengagement and
2 transgressive behavior influence each other.

3 **The Role of Moral Identity on Doping**

4 In line with our hypothesis, moral identity was inversely associated with doping
5 likelihood: Athletes who felt that being a moral person is central to their self-concept were
6 less likely to use banned substances to enhance their performance and recover from injury.
7 This finding supports and extends past work, which has shown a link between moral identity
8 and antisocial behavior in sport (e.g., Kavussanu et al., 2013, 2015), as well as unethical
9 conduct in other contexts (Hertz & Krettenauer, 2016). Like other transgressive acts,
10 doping may be viewed as unethical behavior, which is not compatible with the perception of
11 the (doping) athlete, as a moral person.

12 Another interesting finding of our study was that the relationship between moral
13 identity and doping likelihood was mediated by moral disengagement. The negative
14 association between moral identity and moral disengagement is in line with evidence
15 suggesting that moral identity operates as an antecedent of moral disengagement (e.g.,
16 Detert et al., 2008). Although Bandura (1991, 1999) does not refer to moral identity
17 specifically, he mentions moral standards as important regulators of moral conduct. Moral
18 identity has been proposed as another self-regulatory mechanism (Aquino & Reed, 2002),
19 which may be somewhat similar to the concept of moral standards. Specifically, it is
20 reasonable to assume that people, who have a strong moral identity would also have high
21 moral standards, as these individuals consider being moral (which is translated into doing
22 good things) as important and central to their self-concept. Our findings have theoretical
23 implications and suggest that people who are likely to morally disengage may simply not
24 have very high moral standards and that being a moral person is not that important to them.

The relationship between moral identity and doping likelihood was also mediated by anticipated guilt. This suggests that athletes with a strong moral identity may be deterred from using banned substances, because they would expect to experience intense guilt for acting in this manner. Guilt is an important deterrent of unethical behavior (e.g., Kavussanu et al., 2015; Tangney et al., 2007), and people with a strong moral identity would feel guilty for acting in an unethical manner. The emotional experience elicited by wrongdoing could be augmented by strengthening one's moral identity. Overall, our results underline the important role of moral identity in doping.

Practical Implications

Our findings have some implications for practitioners, who wish to alleviate doping from sport. They clearly show that both moral identity and moral disengagement are indirectly related to doping likelihood via anticipated guilt. Thus, practitioners need to focus on strengthening athletes' moral identity and reduce their tendency to morally disengage. People with a strong moral identity consider being a good or moral person a central part of their self-concept, that is, it is important to them to be moral. To strengthen moral identity, coaches could emphasize the importance of acting in an ethical manner when taking part in sport. They could also reduce moral disengagement by challenging athletes' justifications for doping, and facilitating moral engagement. For example, the distortion of consequences mechanism, exemplified in the statement "doping does not hurt anyone" could be challenged by pointing out that doping does hurt others and is a threat to the integrity of sport, as it compromises fair play. Overall, the findings point to the importance of focusing on moral variables in eliminating doping from sport.

Limitations of the Study and Directions for Future Research

In this study, we reported some interesting findings. However, it is prudent to consider potential limitations when interpreting these findings. First, the sample was

1 characterized by relatively low moral disengagement and doping likelihood. It remains to be
2 seen whether our model holds in athletes with higher scores on these variables. Second, we
3 examined doping likelihood only in relation to two hypothetical scenarios. Future research
4 could investigate the influence of moral cognition and emotion on doping likelihood and
5 intentions across a broad range of situations, including circumstances relating to
6 performance outcomes, sources of influence, and rewards and punishments (see Huybers &
7 Mazanov, 2012).

8 Third, our participants came from a variety of team sports. It would be interesting to
9 examine whether our model is replicated in athletes from a variety of individual sports.

10 Fourth, we did not use a social desirability scale. We did not see the need for this because
11 the questionnaires were completed anonymously, and participants referred to hypothetical
12 situations indicating their doping likelihood, rather than explicitly indicating whether they
13 had used banned substances. Although we are confident that they responded honestly,
14 future research could include a social desirability scale to determine whether responses are
15 affected by social desirability. Finally, we used a cross-sectional design and therefore we
16 cannot make firm assertions about the direction of causality. We can simply say that our
17 mediation analysis provided evidence that is consistent with the conceptual model that we
18 tested. It would be enlightening to attempt to replicate the present findings using
19 longitudinal and experimental designs, which provide clear evidence for the direction of
20 causality.

Endnotes

¹Some of these studies examined doping likelihood rather than doping intention. The term doping intention is used to refer to this work for the sake of conciseness.

²In the UK, where this study was conducted, parental consent is required only for participants younger than 16 years.

³These scenarios were developed and used in research funded by the World Anti-Doping Agency (Kavussanu, Elbe, & Hatzigeorgiadis, 2015).

Table 1

Descriptive Statistics, Alpha Coefficients, and Zero-Order Correlations (N = 398)

Variable	<i>M</i>	<i>SD</i>	α	1.	2.	3.
1. Moral identity	5.89	0.90	.79			
2. Moral disengagement	2.29	1.00	.82	-.33 *		
3. Anticipated guilt	4.69	1.74	.94	.30 *	-.57 *	
4. Doping likelihood	2.53	1.41	.79	-.27 *	.65 *	-.70 *

Note. Possible range of all variables was 1-7. * $p < .001$.

Table 2. *Direct and Indirect Effects on Moral Disengagement, Guilt Doping and Likelihood (N = 398)*

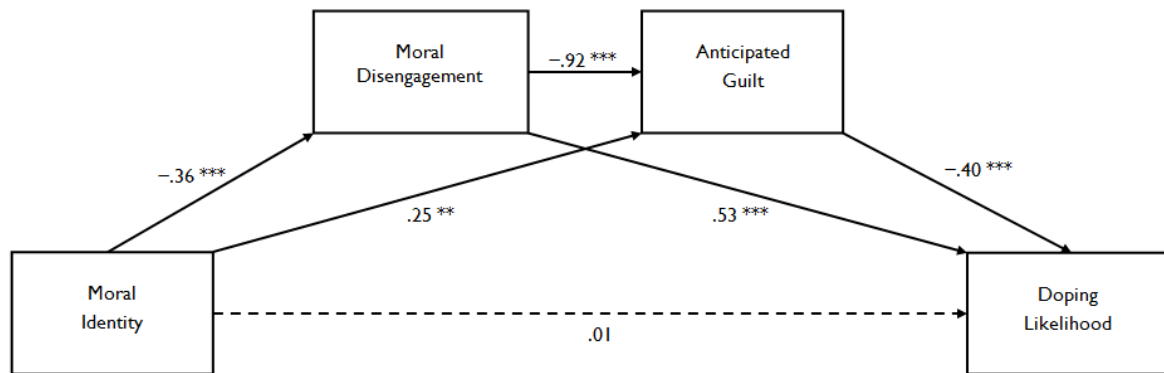

Pathways		B	95% CI	CSIE	95% CI
Direct effects					
MI	→ MD	-.36 ***	-.46, -.26		
	→ Guilt	.25 **	.09, .42		
	→ Doping	.01	-.10, .12		
MD	→ Guilt	-.92 ***	-1.07, -.77		
	→ Doping	.53 ***	.42, .64		
Guilt	→ Doping	-.40 ***	-.46, -.33		
Indirect effects of MD on Doping via					
Guilt		.40*	.31, .50	.28*	.22, .35
Indirect effects of MI on Doping via					
MD		-.19 *	-.29, -.12	-.12 *	-.18, -.08
Guilt		-.10 *	-.18, -.03	-.06 *	-.12, -.02
MD & Guilt		-.13 *	-.20, -.08	-.08 *	-.12, -.05

Note. Unstandardized coefficients are shown. MI = moral identity. MD = moral disengagement. Guilt = anticipated guilt. Doping = doping likelihood. CSIE = completely standardized indirect effect, where .01 = small, .09 = medium, and .25 = large.

* $p < .05$; ** $p < .01$; *** $p < .001$

Figure 1. The Effects of Moral Identity on Doping Likelihood and the Mediating Role of Moral Disengagement and Anticipated Guilt. Note. The values presented are the unstandardized regression coefficients. A solid line represents a significant relationship.

** $p < .01$, *** $p < .001$.
